Basic Types and Formatted I/O
C Variables Names (1)

Variable Names
◆ Names may contain letters, digits and underscores
◆ The first character must be a letter or an underscore.
  – the underscore can be used but watch out!!
◆ Case matters!
◆ C keywords cannot be used as variable names.

```
present, hello, y2x3, r2d3, ... /* OK */
_1993_tar_return  /* OK but don’t */
Hello#there        /* illegal */
double             /* shouldn’t work */
2fartogo           /* illegal */
```
C Variables Names (2)

Suggestions regarding variable names

◆ DO: use variable names that are descriptive
◆ DO: adopt and stick to a standard naming convention
  – sometimes it is useful to do this consistently for the entire software development site

◆ USE short names for local variables
◆ USE long names for global variables
◆ USE standard names for common idioms

◆ AVOID: variable names starting with an underscore
  – often used by the operating system and easy to miss

◆ AVOID: using uppercase only variable names
  – generally these are pre-processor macros (later)
There are only a few basic data types in C

- **char**: a single byte, capable of holding one character
- **int**: an integer of fixed length, typically reflecting the natural size of integers on the host machine (i.e., 16, 32 or 64 bits)
- **float**: single-precision floating point
- **double**: double precision floating point
There are a number of qualifiers which can be applied to the basic types

- length of data
  - short int: "shorter" int, <= number of bits in an int
  - can also just write "short"
  - long int: a "longer int", >= number of bits in an int
  - often the same number of bits as an int
  - can also just write "long"
  - long double: generally extended precision floating point

- signed and unsigned
  - unsigned int: an int type with no sign
  - if int has 32-bits, range from 0..2^{32}-1
  - also works with long and short
  - unsigned char: a number from 0 to 255
  - signed char: a number from –128 to 127 (8-bit signed value)
  - very similar to byte in Java
C Basic Types (3)

- All types have a fixed size associated with them
  - this size can be determined at compile time
- Example storage requirements

<table>
<thead>
<tr>
<th>DATA</th>
<th>Bytes Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>The letter x (char)</td>
<td>1</td>
</tr>
<tr>
<td>The number 100 (int)</td>
<td>4</td>
</tr>
<tr>
<td>The number 120.145 (double)</td>
<td>8</td>
</tr>
</tbody>
</table>

- These numbers are highly variable between C compilers and computer architectures.
- Programs that rely on these figures must be very careful to make their code portable (ie. Try not to avoid relying on the size of the predefined types)
C Basic Types (4)

Numeric Variable Types

◆ Integer Types:
  – Generally 32-bits or 64-bits in length
  – Suppose an int has $b$-bits
    ❖ a signed int is in range $-2^{b-1}..2^{b-1}-1$
      – $-32768 .. 32767$ \((32767+1=-32768)\)
    ❖ an unsigned int is in range $0..2^b-1$
      – $0 .. 65535$ \((65535+1=0)\)
    ❖ no error message is given on this "overflow"

◆ Floating-point Types:
  – \textit{Generally} IEEE 754 floating point numbers (but important exceptions)
    ❖ float (IEEE single): 8 bits exponent, 1-bit sign, 23 bits mantissa
    ❖ double (IEEE double): 10 bits exponent, 1-bit sign, 53 bits mantissa
    ❖ long double (IEEE extended)
  – Only use floating point types when really required
    ❖ they do a lot of rounding which must be understood well
    ❖ floating point operations tend to cost more than integer operations
### C Basic Types (5)

#### A typical 32-bit machine

<table>
<thead>
<tr>
<th>Type</th>
<th>Keyword</th>
<th>Bytes</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>character</td>
<td>char</td>
<td>1</td>
<td>-128...127</td>
</tr>
<tr>
<td>integer</td>
<td>int</td>
<td>4</td>
<td>-2,147,483,648...2,147,438,647</td>
</tr>
<tr>
<td>short integer</td>
<td>short</td>
<td>2</td>
<td>-32,768...32,367</td>
</tr>
<tr>
<td>long integer</td>
<td>long</td>
<td>4</td>
<td>-2,147,483,648...2,147,438,647</td>
</tr>
<tr>
<td>long long integer</td>
<td>long long</td>
<td>8</td>
<td>-9,223,372,036,854,775,808...9,223,372,036,855,807</td>

<td>0...4,294,967,295</td>
</tr>
<tr>
<td>single-precision</td>
<td>float</td>
<td>4</td>
<td>1.2E-38...3.4E38</td>
</tr>
<tr>
<td>double-precision</td>
<td>double</td>
<td>8</td>
<td>2.2E-308...1.8E308</td>
</tr>
</tbody>
</table>
The `printf` function is used to output information (both data from variables and text) to standard output.
- A C library function in the `<stdio.h>` library.
- Takes a format string and parameters for output.

`printf(format string, arg1, arg2, ...);`
- e.g. `printf("The result is %d and %d\n", a, b);`

The format string contains:
- Literal text: is printed as is without variation
- Escaped sequences: special characters preceded by `\`
- Conversion specifiers: `%` followed by a single character
  - Indicates (usually) that a variable is to be printed at this location in the output stream.
  - The variables to be printed must appear in the parameters to `printf` following the format string, in the order that they appear in the format string.
## Formatted Printing with printf (2)

### Conversion Specifiers

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%c</code></td>
<td>Single character</td>
</tr>
<tr>
<td><code>%d</code></td>
<td>Signed decimal integer</td>
</tr>
<tr>
<td><code>%x</code></td>
<td>Hexadecimal number</td>
</tr>
<tr>
<td><code>%f</code></td>
<td>Decimal floating point number</td>
</tr>
<tr>
<td><code>%e</code></td>
<td>Floating point in “scientific notation”</td>
</tr>
<tr>
<td><code>%s</code></td>
<td>Character string (more on this later)</td>
</tr>
<tr>
<td><code>%u</code></td>
<td>Unsigned decimal integer</td>
</tr>
<tr>
<td><code>%%</code></td>
<td>Just print a % sign</td>
</tr>
<tr>
<td><code>%ld</code>, <code>%lld</code></td>
<td>long, and long long</td>
</tr>
</tbody>
</table>

- There must be one conversion specifier for each argument being printed out.
- Ensure you use the correct specifier for the type of data you are printing.
Formatted Printing with printf (3)

- **Escape Sequences:**

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\a</td>
<td>Bell (alert)</td>
</tr>
<tr>
<td>\b</td>
<td>Backspace</td>
</tr>
<tr>
<td>\n</td>
<td>Newline</td>
</tr>
<tr>
<td>\t</td>
<td>Horizontal tab</td>
</tr>
<tr>
<td>\</td>
<td>Backslash</td>
</tr>
<tr>
<td>'</td>
<td>Single quote</td>
</tr>
<tr>
<td>&quot;</td>
<td>Double quotation</td>
</tr>
<tr>
<td>\xhh</td>
<td>ASCII char specified by hex digits hh</td>
</tr>
<tr>
<td>\ooo</td>
<td>ASCII char specified by octal digits ooo</td>
</tr>
</tbody>
</table>
An example use of `printf`

```c
#include <stdio.h>
int main() {
    int ten=10, x=42;
    char ch1='o', ch2='f';
    printf("%d%%% %c%c %d is %f\n",
            ten, ch1, ch2, x, 1.0*x / ten);
    return 0;
}
```

What is the output?

Why do we need to do this? We will talk about a better way later. (Type conversion)
Reading Numeric Data with scanf (1)

- The `scanf` function is the input equivalent of `printf`
  - A C library function in the `<stdio.h>` library
  - Takes a format string and parameters, much like `printf`
  - The format string specifiers are nearly the same as those used in `printf`

- Examples:
  
  ```c
  scanf("%d", &x);       /* reads a decimal integer */
  scanf("%f", &rate);   /* reads a floating point value */
  ```

- The ampersand (&) is used to get the “address” of the variable
  - All the C function parameters are “passed by value”.
  - If we used `scanf("%d",x)` instead, the value of x is passed. As a result, `scanf` will not know where to put the number it reads.
  - More about this in Section 17 (“Functions”)

Reading Numeric Data with scanf (2)

◆ Reading more than one variable at a time:
  – For example:
    ```c
    int n1, n2;  float f;
    scanf("%d%d%f",&n1,&n2,&f);
    ```
  – Use white spaces to separate numbers when input.
    ```c
    5      10      20.3
    ```

◆ In the format string:
  – You can use other characters to separate the numbers
    ```c
    scanf("value=%d,ratio=%f", &value,&ratio);
    ```
    ✤ You must provide input like:
    ```c
    value=27,ratio=0.8
    ```
  – scanf returns an int
    ✤ If end-of-file was reached, it returns EOF, a constant defined in <stdio.h>
    ✤ Otherwise, it returns the number of input values correctly read from standard input.
One tricky point:
- If you are reading into a `long` or a `double`, you must precede
  the conversion specifier with an `l` (a lower case L)
- Example:
  ```c
  int main() {
    int x;
    long y;
    float a;
    double b;
    scanf("%d %ld %f %lf", &x, &y, &a, &b);
    return 0;
  }
  ```
Type Conversion

- C allows for conversions between the basic types, implicitly or explicitly.
- Explicit conversion uses the cast operator.
- Example 1:
  ```c
  int x=10;
  float y,z=3.14;
  y=(float) x;    /* y=10.0 */
  x=(int) z;      /* x=3 */
  x=(int) (-z);   /* x=-3 -- rounded approaching zero */
  ```
- Example 2:
  ```c
  int i;
  short int j=1000;
  i=j*j;        /* wrong!!! */
  i=(int)j * (int)j;  /* correct */
  ```
Implicit Conversion

- If the compiler expects one type at a position, but another type is provided, then implicit conversion occurs.
- Conversion during assignments:
  ```
  char c='a';
  int i;
  i=c;    /* i is assigned the ASCII code of ‘a’ */
  ```
- Arithmetic conversion – if two operands of a binary operator are not the same type, implicit conversion occurs:
  ```
  int i=5 , j=1;
  float x=1.0 , y;
  y = x / i;       /* y = 1.0 / 5.0 */
  y = j / i;       /* y = 1 / 5 so y = 0 */
  y = (float) j / i; /* y = 1.0 / 5 */
  /* The cast operator has a higher precedence */
  ```
Example

The `sizeof()` function returns the number of bytes in a data type.

```c
int main() {
    printf("Size of char ........ = %2d byte(s)\n", sizeof(char));
    printf("Size of short ........ = %2d byte(s)\n", sizeof(short));
    printf("Size of int ........... = %2d byte(s)\n", sizeof(int));
    printf("Size of long long ....... = %2d byte(s)\n", sizeof(long long));
    printf("Size of long ........ = %2d byte(s)\n", sizeof(long));
    printf("Size of unsigned char. = %2d byte(s)\n", sizeof(unsigned char));
    printf("Size of unsigned int.. = %2d byte(s)\n", sizeof(unsigned int));
    printf("Size of unsigned short = %2d byte(s)\n", sizeof(unsigned short));
    printf("Size of unsigned long. = %2d byte(s)\n", sizeof(unsigned long));
    printf("Size of float ........ = %2d byte(s)\n", sizeof(float));
    printf("Size of double ........ = %2d byte(s)\n", sizeof(double));
    printf("Size of long double .. = %2d byte(s)\n", sizeof(long double));
    return 0;
}
```
Example

Results of a previous run of this code on obelix ... 

- Size of char = 1 byte(s)
- Size of short = 2 byte(s)
- Size of int = 4 byte(s)
- Size of long = 4 byte(s)
- Size of long long = 8 byte(s)
- Size of unsigned char = 1 byte(s)
- Size of unsigned int = 4 byte(s)
- Size of unsigned short = 2 byte(s)
- Size of unsigned long = 4 byte(s)
- Size of float = 4 byte(s)
- Size of double = 8 byte(s)
- Size of long double = 16 byte(s)
Creating Simple Types

- **typedef** creates a new name for an existing type
  - Allows you to create a new name for a complex old name

- Generic syntax
  ```c
  typedef oldtype newtype;
  ```

- Examples:
  ```c
  typedef long int32;    /* suppose we know an int has 32-bits */
  typedef unsigned char  byte;  /* create a byte type */
  typedef long double extended;
  ```

- These are often used with complex data types
  - Simplifies syntax!
Variable Declaration (1)

- **Generic Form**
  
  `typename varname1, varname2, ...;`

- **Examples:**
  
  ```
  int count;
  float a;
  double percent, total;
  unsigned char x,y,z;
  long int aLongInt;
  long AnotherLongInt
  unsigned long a_1, a_2, a_3;
  unsigned long int b_1, b_2, b_3;
  typedef long int32;
  int32 n;
  ```

- **Where declarations appear affects their scope and visibility**
  
  - Rules are similar to those in Java
  - Declaration outside of any function are for global variables
    
    - e.g., just before the main routine
Variable Declaration (2)

Initialization

- ALWAYS initialize a variable before using it
  - Failure to do so in C is asking for trouble
  - C does not force you to initialize variables before using them, but…
  - The value of an uninitialized variables is undefined in the C standards

- Examples:
  
  ```c
  int count;   /* Set aside storage space for count */
  count = 0;   /* Store 0 in count */
  
  This can be done at definition:
  ```
  
  ```c
  int count = 0;
  double percent = 10.0, rate = 0.56;
  
  Warning: be careful about “out of range errors”
  ```
  
  ```c
  unsigned int value = -2500;
  ```
  - The C compiler does not detect this as an error
    - What do you suspect it does?
Constants (1)

Constants

- You can also declare variables as being constants
  - Use the `const` qualifier:
    
    ```
    const double pi=3.1415926;
    const int maxlength=2356;
    const int val=(3*7+6)*5;
    ```
  - Constants are useful for a number of reasons
    - Tells the reader of the code that a value does not change
    - Makes reading large pieces of code easier
    - Tells the compiler that a value does not change
    - The compiler can potentially compile faster code

- Use constants whenever appropriate
- Be very careful with pointers to constants
Preprocessor Constants

- These are an older form of constant which you still see
  - There is a potential for problems, so be careful using them!
- Generic Form:
  ```c
  #define CONSTNAME literal
  ```
  - Generally make pre-processor constants all upper case (convention).
- Example:
  ```c
  #define PI 3.14159
  ```
- What really happens
  - The C preprocessor runs before the compiler.
  - Every time it sees the token PI, it substitutes the value 3.14159.
  - The compiler is then run with this “pre-processed” C code.
- Why this is dangerous?
  - Hard to determine the value of a multiply-defined constant (which you are allowed to create)
An example of constants in use:

```c
#include <stdio.h>
#define GRAMS_PER_POUND 454
const int FARFARAWAY = 3000;
int main ()
{
    int weight_in_grams, weight_in_pounds;
    int year_of_birth, age_in_3000;
    printf("Enter your weight in pounds: ");
    scanf("%d", &weight_in_pounds);
    printf("Enter your year of birth: ");
    scanf("%d", &year_of_birth);
    weight_in_grams = weight_in_pounds * GRAMS_PER_POUND;
    age_in_3000 = FARFARAWAY - year_of_birth;
    printf("Your weight in grams = %d\n", weight_in_grams);
    printf("In 3000 you will be %d years old\n", age_in_3000);
    return 0;
}
```
Literals in C

- Literals are representations of values of some types
  - C allows literal values for integer, character, and floating point types

- Integer literals
  - Just write the integer in base 10
    ```
    int y = -46;
    ```
  - We will discuss base 8 and base 16 literals later

- Character literals
  - Character literals are specified with a single character in single quotes
    ```
    char ch = 'a';
    ```
  - Special characters are specified with escape characters
    - Recall the discussion of ‘escaped’ characters with the shell
    - We will discuss these later

- Floating point literals
  - Just write the floating point number
    ```
    float PI = 3.14159;
    ```
  - Can also use mantissa/exponent (scientific) notation
    ```
    double minusPItimes100 = -3.14159e2
    ```
