Microprocessor Design Trends

• Joy's Law [Bill Joy of BSD4.x and Sun fame]

\[
\text{MIPS} = 2^{\text{year} - 1984}
\]

• Millions of instructions per second [MIPS] executed by a single chip microprocessor

• More realistic rate is a doubling of MIPS every 18 months [or a quadrupling every 3 years]

• What ideas and techniques in new microprocessor designs have contributed to this continued rate of improvement?
Some of improvements made over the last 40 years ...

- smaller VLSI feature sizes [1 micron (μ) ... 7nm]
- increased clock rate [1MHz ... 4GHz]
- reduced vs complex instruction sets [RISC vs CISC]
- faster memory access modes (eg burst accesses)
- integrated on-chip MMUs, FPUs, ...
- pipelining
- superscalar [multiple instructions/clock cycle]
- multi-level on-chip instruction and data caches
- streaming SIMD [single instruction multiple data] instruction extensions [MMX, SSEx]
- hyper threading, multi-core and multiprocessor support
- direct programming of graphics co-processor
- high speed point to point interconnect [Intel QuickPath, AMD HyperTransport]
- solid state disks
- ...

IA32 [Intel Architecture 32 bit]

• IA32 first released in 1985 with the 80386 microprocessor

• IA32 still used today by current Intel CPUs

• modern Intel CPUs have many additions to the original IA32 including MMX, SSE1, SSE2, SSE3, SSE4, SSE5, AVX, AVX2 and AVX512 [Streaming SIMD Extensions] and an extended 64 bit instruction set when operating in 64 bit mode [named IA-32e or IA-32e or x64]

• 32 bit CPU [performs 8, 16 and 32 bit integer + 32 and 64 bit floating point arithmetic]

• 32 bit virtual and physical address space $2^{32}$ bytes [4GB]

• each instruction a multiple of bytes in length [from 1 to 17+]
Registers [far fewer than a typical RISC]

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eax</td>
<td>accumulator</td>
</tr>
<tr>
<td>ebx</td>
<td></td>
</tr>
<tr>

<td>eip</td>
<td>instruction pointer [pc]</td>
</tr>
</tbody>
</table>

**general purpose registers**

normally used as memory address registers

NB: floating point and SSE registers, ... not shown
Registers...

- "e" in eax = extended = 32bits

- possible to access 8 and 16 bit parts of eax, ebx, ecx and edx using alternate register names ah, al and ax
Instruction Format

- two address [will use Microsoft assembly language syntax used by VC++, MASM]
  
  ```
  add   eax, ebx    ; eax = eax + ebx [right to left]
  ```

- alternative gnu syntax
  
  ```
  addl  %ebx, %eax  ; eax = eax + ebx [left to right]
  ```

- two operands normally
  
  register/register
  register/immediate
  register/memory
  memory/register

- memory/memory and memory/immediate are NOT allowed
### Supported Addressing Modes

<table>
<thead>
<tr>
<th>addressing mode</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>immediate</td>
<td>mov eax, ( n )</td>
</tr>
<tr>
<td>register</td>
<td>mov eax, ebx</td>
</tr>
<tr>
<td>direct/absolute</td>
<td>mov eax, [( a )]</td>
</tr>
<tr>
<td>indexed</td>
<td>mov eax, [ebx]</td>
</tr>
<tr>
<td>indexed</td>
<td>mov eax, [ebx+( n )]</td>
</tr>
<tr>
<td>scaled indexed</td>
<td>mov eax, [ebx*( s )+( n )]</td>
</tr>
<tr>
<td>scaled indexed</td>
<td>mov eax, [ebx+ecx]</td>
</tr>
<tr>
<td>scaled indexed</td>
<td>mov eax, [ebx+ecx*( s )+( n )]</td>
</tr>
</tbody>
</table>

- address computed as the sum of a register, a scaled register and a 1, 2 or 4 byte signed constant \( n \); can use most registers
- scaled indexed addressing used to index into arrays
- scaling constant \( s \) can be 1, 2, 4 or 8

\([a] = \text{contents of memory address } a\)
IA32 AND X64

IA32 basic instruction set

- **mov** move
- **xchg** exchange
- **add** add
- **sub** subtract
- **cdq** convert double to quadword
- **idiv** unsigned divide
- **imul** signed multiply
- **inc** increment by 1
- **dec** decrement by 1
- **neg** negate
- **cmp** compare
- **lea** load effective address
- **test** AND operands and set flags
- **and** and
- **or** or
- **xor** exclusive or
- **not** not
- **push** push onto stack
- **pop** pop from stack
- **sar** shift arithmetic right
- **shl** shift logical left
- **shr** shift logical right
- **jmp** unconditional jump
- **j {e, ne, l, le, g, ge}** signed jump
- **j {b, be, a, ae}** unsigned jump
- **call** call subroutine
- **ret** return from subroutine

- SHOULD BE ENOUGH INSTRUCTIONS TO COMPLETE TUTORIALS

IA32 Assembly Language examples

- size of operation can often be determined implicitly by MASM, but when unable to do so, size needs to be specified explicitly

  \begin{align*}
  \text{mov} & \quad \text{eax}, [ebp+8] \quad ; \text{implicitly 32 bit [as eax is 32 bits]} \\
  \text{mov} & \quad \text{ah}, [ebp+8] \quad ; \text{implicitly 8 bit [as ah is 8 bits]} \\
  \text{dec} & \quad [ebp+8] \quad ; \text{decrement memory location [ebp+8] by 1} \\
  & \quad ; \text{assembler unable to determine operand size} \\
  & \quad ; \text{is it an 8, 16 or 32 bit value??} \\
  \text{dec} & \quad \text{DWORD PTR [ebp+8]} \quad ; \text{make explicitly 32 bit} \\
  \text{dec} & \quad \text{WORD PTR [ebp+8]} \quad ; \text{make explicitly 16 bit} \\
  \text{dec} & \quad \text{BYTE PTR [ebp+8]} \quad ; \text{make explicitly 8 bit}
  \end{align*}

NB: unusual assembly language syntax
IA32 AND X64

IA32 Assembly Language examples ...

• memory/immediate operations NOT allowed

  mov [ebp+8], 123 ; NOT allowed and operation size ALSO unknown
  mov eax, 123 ; use 2 instructions instead...
  mov [ebp+8], eax ; implicitly 32 bits

• lea [load effective address] is a useful instruction for performing simple arithmetic

  lea eax, [ebx+ecx*4+16] ; eax = ebx+ecx*4+16

• does the effective address calculation, but doesn’t access memory
IA32 Assembly Language examples ...

• quickest way to clear a register?

  xor   eax, eax ; exclusive OR with itself
  mov   eax, 0 ; instruction occupies more bytes and...
               ; probably takes longer to execute

• quickest way to test if a register is zero?
  NB: mov instruction doesn’t update the condition code flags

  test  eax, eax ; AND eax with itself, set flags and...
  je     ... ; jump if zero
Function/Procedure Calling

reminder of the steps normally carried out during a function/procedure call and return

- pass parameters [IA32: evaluate and push on stack]
- enter new function [IA32: push return address and jump to first instruction of function]
- allocate space for local variables [IA32: on stack by decrementing esp]
- save registers [IA32: on stack]

<function body>

- restore saved registers [IA32: from stack]
- de-allocate space for local variables [IA32: increment esp]
- return to calling function [IA32: pop return address from stack]
- remove parameters [IA32: increment esp]
IA32 Function Stack Frame

- stack frame after call to \( f(p_0, p_1, p_2) \)
- stack grows down in memory [from highest address to lowest]
- parameters pushed right to left
- NB: stack always aligned on a 4 byte boundary [it's not possible to push a single byte]
- ebp used as a frame pointer parameters and locals accessed relative to ebp [\( p_0 @ \text{ebp+8} \)]
IA32 Calling Conventions

• several IA32 procedure/function calling conventions

• will use Microsoft _cdecl calling convention [as per previous diagram] so C/C++ and IA32 assembly language code can mixed
  ▪ function result returned in eax
  ▪ eax, ecx and edx considered volatile and are NOT preserved across function calls, others registers need to be saved and restored if used
  ▪ caller removes parameters

• why are parameters pushed right-to-left??

  C/C++ pushes parameters right-to-left so functions like `printf(char *formats, ...) [which can accept an arbitrary numbers of parameters]` can be handled more easily since the first parameter is always stored at [ebp+8] irrespective of how many parameters are pushed
Accessing Parameters and Local Variables

- ebp used as a frame pointer
- parameters and local variables accessed at offsets from ebp

- can avoid using a frame pointer [normally for speed] by accessing parameters and locals variables relative to the stack pointer, but more difficult because the stack pointer can change during execution [BUT easy for a compiler to track]

- parameters accessed with +ve offsets from ebp [see stack frame diagram]

  p0 @ [ebp+8]
  p1 @ [ebp+12]
  ...

- local variables accessed with –ve offsets from ebp [see stack frame diagram]

  local variable 0 @ [ebp-4]
  local variable 1 @ [ebp-8]
  ...
Consider the IA32 Code for a Simple Function

```c
int f (int p0, int p1, int p2) {    // parameters
    int x, y;                    // local variables
    x = p0 + p1;
    ...                         // result
    return x + y;
}
```

- a call f(p0, p1, p2) matches stack frame diagram on previous slide
- 3 parameters `p0, p1` and `p2` and 2 local variables `x` and `y`

- need to generate code for
  - *calling function f*
  - *function f entry*
  - *function f body*
  - *function f exit*
IA32 Code to Call Function f

- parameters $p_0$, $p_1$ and $p_2$ pushed onto stack by caller right to left

```
f(1, 2, 3)
push 3 ; push immediate values...
push 2 ; right to left
push 1
call f ; call f
add esp, 12 ; add 12 to esp to remove parameters from stack
```

push return address and jump to f
Function Entry

- need instructions to save ebp [old frame pointer] and ...
- initialize ebp [new frame pointer] and ...
- allocate space for local variables on stack and ...
- push non volatile registers used by function onto stack

```assembly
f:     push   ebp       ; save ebp
       mov    ebp, esp ; ebp -> new stack frame
       sub    esp, 8   ; allocate space for locals x and y
       push   ebx      ; save non volatile registers used by function

<function body>         ; function body

<function exit>         ; function exit
```

NB: _cdecl convention means there is NO need to save eax, ecx and edx
Function Body

• parameters pushed on stack and ...
• space already allocated for local variables

parameters p0 @ [ebp+8] and p1 @ [ebp+12]
locals x @ [ebp-4] and y @ [ebp-8]

• \( x = p0 + p1 \)

\[
\begin{align*}
& \text{mov} \quad \text{eax}, \ [ebp+8] \quad ; \text{eax} = p0 \\
& \text{add} \quad \text{eax}, \ [ebp+12] \quad ; \text{eax} = p0 + p1 \\
& \text{mov} \quad [ebp-4], \ \text{eax} \quad ; \ x = p0 + p1
\end{align*}
\]

• return \( x + y \);

\[
\begin{align*}
& \text{mov} \quad \text{eax}, \ [ebp-4] \quad ; \text{eax} = x \\
& \text{add} \quad \text{eax}, \ [ebp-8] \quad ; \text{eax} = x + y
\end{align*}
\]

NB: result returned in eax
Function Exit

• need instructions to unwind stack frame at function exit

... 

\[ \text{pop \ } ebx \] ; restore saved registers
\[ \text{mov \ esp, ebp} \] ; restore esp
\[ \text{pop \ ebp} \] ; restore previous ebp
\[ \text{ret \ 0} \] ; return from function

• ret pops return address from stack and...
• adds integer parameter to esp [used to remove parameters from stack]
• if integer parameter not specified, defaults to 0

• since using \_cdecl\ convention caller will remove parameters from stack

• make sure you know why a stack frame needs to be created for each function call
IA32 Code for Accessing an Array

```c
int a[100]; // global array of int

main(...) {
    a[1] = a[2] + 3; // constant indices
}
```

- int is 4 bytes
- assume array a is stored at absolute address a (eg. a = 0x10000)
- a[0] store at address a, a[1] at a+4, a[2] at a+8, a[n] at a+n*4

```assembly
mov eax, [a+8]; // eax = a[2] assembler computes a + 8
add eax, 3 // eax = a[2] + 3
mov [a+4], eax // a[1] = a[2] + 3
```
IA32 Code for Accessing an Array …

```c
int *a = (int*) malloc(100*sizeof(int));    // array allocated on heap

int p() {
    int i = ...;                           // local variable i @ [ebp-4]
    int j = ...;                           // local variable j @ [ebp-8]
    ...
    a[i] = a[j] + 3;                       // variable indices
}
```

- assume global variable `a` contains the address of the array allocated on heap

```assembly
    mov    edx, [a]                       // edx -> a
    mov    eax, [ebp-8]                   // eax = j
    mov    eax, [edx+eax*4]               // eax = a[j]
    add    eax, 3                         // eax = a[j]+3
    mov    ecx, [ebp-4]                   // ecx = i
    mov    [edx+ecx*4], eax               // a[i] = a[j]+3
```

Tutorial 1 (next lecture)

- mixing C/C++ and IA32 Assembly Language
- example using Visual Studio, VC++ and MASM
- you have to write IA32 assembly language functions min(int, int, int), p(int, int, int, int) and gcd(int, int) [create files t1.h and t1.asm]
- you are given a “main” program t1Test.cpp which will call and test the functions you have written
- you are also given files fib32.h and fib32.asm as an example of how to write an IA32 assembly language function (1) fib32.h contains the function definition (signature) and (2) fib32.asm contains the assembly language for the function fib(int) which calculates the n\textsuperscript{th} Fibonacci number
- t1Test.cpp also contains a C/C++ versions of fib(int)
Tutorial 1 ...

• create a VC++ Win32 Console Application [call it t1Test and specify that it creates a “main” file called t1Test.cpp]

• select project name (t1Test), click on Project menu, select "Build Customizations..." and tick masm

• paste the contents of the file t1Test.cpp from the web into the project file t1Test.cpp

• copy the files fib32.h and fib32.asm into the project directory and add them to the project [Project][Add Existing Item...]

• you can create your t1.h and t1.asm externally and include them into the project using [Project][Add Existing Item...]

• right click on the .asm files to make sure [Properties][General][Item Type] is set to Microsoft Macro Assembler
Tutorial 1 ...

fib32.h

- declares $\text{fib}_{\text{IA32}}(\text{int})$ and $\text{fib}_{\text{IA32}}(\text{int})$ as external C functions so they can be called from a C/C++ program

```c
extern "C" int _cdecl fib_IA32a(int);  // external function
```

- specify extern "C" because C++ function names have extra characters which encode their result and parameter types

fib32.asm

- $\text{fib}_{\text{IA32}}(\text{int})$ – simulating mechanical Debug mode code generation
- $\text{fib}_{\text{IA32}}(\text{int})$ – simulating optimized Release mode code generation
- MASM specific directives at start of file
- .data and .code sections
- public
Tutorial 1 ...

- t1Test.cpp [_tmain]
- #include fib32.h and t1.h
- calls fib_IA32a(n) and fib_IA32b(n) like any other C/C++ function
- file also contains
  1) a C++ version of fib(n) and...
  2) a version of fib(n) that mixes C/C++ and IA32 assembly language using the IA32 inline assembler supported by the VC++ compiler
- calls ALL versions of fib(n) for n = 1 to 20
- Visual Studio automatically compiles t1Test.cpp, assembles fib32.asm and t1.cpp and links them to produce an executable which is then run
- **WARNING**: Visual Studio on SCSS machines (eg. ICT Huts) has problems when source files are stored on a Network drive
Tutorial 1...

- make sure the configuration is x86 [you can delete the default x64 configuration as it is NOT applicable in this case]

x86 (or x64) Debug or Release mode

- how to see the code generated by the VC++ compiler??
  - right click on C/C++ file name [Properties] [C/C++] [Output Files] [Assembler Output] and select Assembly, Machine Code and Source [listing has a .cod extension]
  
- code generated in Debug and Release mode is different
Tutorial 1...

- you will need to define an the external global variable gin t.h

  ```c
  extern "C" int g;  // external global variable g
  ```

- and you will also need to declare g in t1.asm

  ```asm
  .data
  public g     ; start of a data section
  g DWORD 4    ; export variable g
  .code
  g DWORD 4    ; declare global variable g initialised to 4
  ```

- setting breakpoints in .asm file
  - setting breakpoints in an assembly source file hasn't worked properly since VS2013
  - to debug min (for example), set breakpoint in .cpp file on the call to min
  - when breakpoint reached, select [Debug][Windows][Disassembly]
  - THEN single step using F11
  - hover mouse over register names to see their values etc.
